Using git & github is simple.It is just a matter of simple commands and following a correct pattern. In this session, we'll learn how to use git & github from scratch.

#First let's learn how to install git in your machine, remember Kali linux comes with git pre-installed.

#First we start with configuration commands, in your terminal run this commands sequentially.

1.git config --global user.name "Adamstudios"
2.git config --global user.email "Adamstudios254@gmail.com"

#Initializing a project we use *'git init'* command. That is 'git init -b main (This creates a local git repository with a branch name main.

- **Remember that you only need to initialize your project once.) 1.git init -b main**

#check status using 'git status' command to see te files listed as untracked.

1.git status

#Next you need to stage your files. Here we use "git add' command, that is :
-- git add file dir/name' Example...git add git-practice/git.pdf

(check status again using 'git status' command)

#Next we commit our changes. Here we use *'git commit -m'* command. Example…
--git commit -m "we documented our first git project"

#Next you can inspect the history by using the 'git log --oneline' command. That is:
-- git log --oneline.

*******How to push your local project to github *******

- → **Step1.**First create a repository on the github account. It can be done through the terminal but using a github account is easy and faster.
- → **Step2**.You change the directory to the one containing your project.
- → **Step3**.Check the repository and commit history. Example...git status && git log --oneline (sequentially)
- → **Step4.**git add e.g git.pdf
- → ***Step5**.git commit -m "Add some information regarding the project"
- → **Step6.**You connect to your existing repository. First check whether a remote is already configured: Example...git remote -v If nothing appears, add your repository URL: git remote add origin https://github.com/your username/repository name.git

#remember to replace your username with the actual username in your github account, the same to the repository name.

- → **Step6.**Now push to github. Example...git push -u main (If your branch has another name check using 'git branch –show-current')

*****How to pull a file from github*****

- **Step1.** Go to project directory.
- **Step2.**git pull origin main
- **step3.**deleting a file from github
- **step4**.check if you're in the correct repository
- git status & git remote -v
- This commands deletes the file from your github and local repository
- git rm git.pdf
- git commit -m "Remove damaged PDF"
- git push origin main

-This stages the file deletion, records it in Git history, and pushes that deletion to GitHub. The repository itself remains.

Step5.If you want to keep the file in your computer but delete it from your github

- git rm --cached git.pdf
- git commit -m "Remove PDF from repository"
- git push origin main

 - The --cached option removes the file from Git's tracked files without deleting your local copy.

If the file is inside a subdirectory, include its relative path, for example documents/git.pdf.
